**ABSTRACT:** Let G = (V, E) be a simple graph. A set  $D \subseteq V$  is a strong dominating set of G, if for every vertex  $x \in V \setminus D$  there is a vertex  $y \in D$  with  $xy \in E(G)$  and  $\deg(x) \leq \deg(y)$ . The strong domination number  $\gamma_{\rm st}(G)$  is defined as the minimum cardinality of a strong dominating set. In this paper, we study the effects on  $\gamma_{\rm st}(G)$  when G is modified by operations on vertices and edges of G.

Strong domination number Strong dominating set Vertex contraction

MSC (2020):

#### 1. Introduction

A dominating set of a graph G = (V, E) is a subset D of V such that every vertex in  $V \setminus D$  is adjacent to at least one member of D. The minimum cardinality of all dominating sets of G is called the domination number of G and is denoted by  $\gamma(G)$ . This parameter has been extensively studied in the literature and there are hundreds of papers concerned with domination. For a detailed treatment of domination theory, the reader is referred to [6]. Also, the concept of domination and related invariants has been generalized in many ways.

A set  $D \subseteq V$  is a strong dominating set of G, if for every vertex  $x \in V \setminus D$  there is a vertex  $y \in D$  with  $xy \in E$  and  $\deg(x) \leq \deg(y)$  (in this case we say that the vertex y strong dominate the vertex x). The strong domination number  $\gamma_{st}(G)$  is defined as the minimum cardinality of a strong dominating set. A strong dominating set with cardinality  $\gamma_{st}(G)$  is called a  $\gamma_{st}$ -set. The strong domination number was introduced in [7] and some upper bounds on this parameter were presented in [8, 7]. Similar to strong domination number, a set  $D \subset V$  is a weak dominating set of G, if every vertex  $v \in V \setminus D$  is adjacent to a vertex  $u \in D$  such that  $\deg(v) \geq \deg(u)$  (see [5]). The minimum cardinality of a weak dominating set of G is denoted by  $\gamma_w(G)$ . Boutrig and Chellali proved that the relation  $\gamma_w(G) + \frac{3}{\Delta+1}\gamma_{st}(G) \leq n$  holds for any connected graph of order  $n \geq 3$  ([5]). Alikhani, Ghanbari and Zaherifard [3]

examined the effects on  $\gamma_{st}(G)$  when G is modified by edge deletion, edge subdivision and edge contraction. Also they studied the strong domination number of k-subdivision of G.

Motivated by counting of the number of dominating sets of a graph and domination polynomial (see e.g. [1, 4]), the number of the strong dominating sets for certain graphs has been studied in [9].

Let e be an edge of a connected simple graph G. The graph obtained by removing an edge e from G is denoted by G - e. The edge subdivision operation for an edge  $\{u, v\} \in E$  is the deletion of  $\{u, v\}$  from G and the addition of two edges  $\{u, w\}$  and  $\{w, v\}$  along with the new vertex w. A graph which has been derived from G by deleting a vertex v is denoted by G - v. The contraction of v in G denoted by G/v is the graph obtained by deleting v and putting a clique on the (open) neighbourhood of v. An edge contraction is an operation that removes an edge from G while simultaneously merging the two vertices that it previously joined. The obtained graph is denoted as G/e.

In this paper, we examine the effects on  $\gamma_{st}(G)$  when G is modified by operations such as vertex deletion, vertex contraction and edge contraction

### 2. Main Results

In this section, we study the effects on  $\gamma_{st}(G)$  when G is modified by some operations. Before we state our results, we start with a simple example.

**Example 2.1.** Consider star graph  $S_n = K_{1,n}$  as shown in Figure 1. Let  $D = \{u\}$ . Then D is a strong dominating set of  $S_n$ , because  $\deg(u) \ge \deg(v_i)$  and u strong dominates  $v_i$ , for i = 1, 2, ..., n. Therefore  $\gamma_{st}(S_n) = 1$ . Also, for empty graph  $\overline{K_n}$ , since all vertices are isolated vertices, we have  $\gamma_{st}(\overline{K_n}) = n$ .

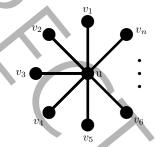

Figure 1: Star graph  $S_n$ 

Now, we consider the vertex deletion.

**Theorem 2.1.** If G = (V, E) is a connected graph and  $v \in V$ , then

$$\gamma_{\rm st}(G) - \deg(v) \le \gamma_{\rm st}(G - v) \le \gamma_{\rm st}(G) + \deg(v) - 1.$$

Furthermore, these bounds are tight.

**Proof.** First we consider the upper bound. Suppose that D is a  $\gamma_{\rm st}$ -set of G. If  $v \in D$ , then  $(D \cup N(v)) \setminus \{v\}$  is a strong dominating set of G - v and we are done. If  $v \notin D$ , then there exists  $u \in N(v)$  such that u strong dominate v. So  $D \cup N(v)$  is a strong dominating set with size at most  $\gamma_{\rm st}(G) + \deg(v) - 1$ . Therefore we have  $\gamma_{\rm st}(G - v) \leq \gamma_{\rm st}(G) + \deg(v) - 1$ . The equality holds for the star graph, and v is the universal vertex. Now, we obtain the lower bound. First we consider G - v and suppose that S is a  $\gamma_{\rm st}$ -set of G - v. We have two cases for v in G:

- (i)  $\deg(v) > \deg(u)$  for all  $u \in N(v)$ . Then clearly  $S \cup \{v\}$  is a strong dominating set for G. So  $\gamma_{\rm st}(G) \le \gamma_{\rm st}(G-v) + 1$ .
- (ii) There exists  $u \in N(v)$  such that  $\deg(u) \ge \deg(v)$ . So  $S \cup N(v)$  is a strong dominating set for G and so  $\gamma_{\rm st}(G) \le \gamma_{\rm st}(G-v) + \deg(v)$ .

Therefore we have  $\gamma_{\rm st}(G-v) \geq \gamma_{\rm st}(G) - \deg(v)$ . Now, we show that this bound is tight. Consider Figure 2. The set of black vertices is a  $\gamma_{\rm st}$ -set of G, say D, and we have  $\gamma_{\rm st}(G) = 18$ . Now,  $D \setminus N(v)$  is a  $\gamma_{\rm st}$ -set of G-v, and  $\gamma_{\rm st}(G-v) = 15$ . Therefore we have the result.

The following theorem gives bounds for the strong domination number of a graph G/v, where G/v is a graph obtained by G and contraction of a vertex v. We recall that a vertex v is a pendant vertex, if  $\deg(v) = 1$ .

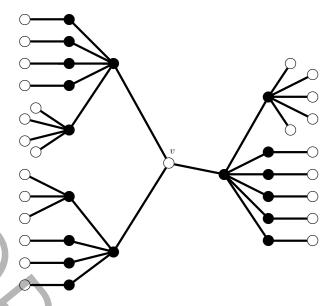

Figure 2: Graph G with  $\gamma_{\rm st}(G) = 18$  and  $\gamma_{\rm st}(G - v) = 15$ .

**Theorem 2.2.** If G = (V, E) is a connected graph and  $v \in V$  is not a pendant vertex, then

$$\gamma_{\rm st}(G) - \deg(v) + 1 \le \gamma_{\rm st}(G/v) \le \gamma_{\rm st}(G) + 1.$$

Furthermore, these bounds are tight.

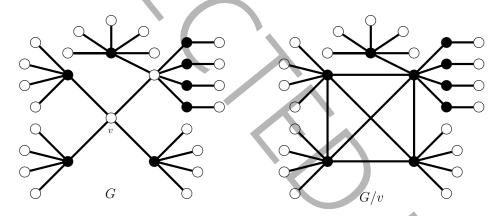

Figure 3: Graphs G and G/v with  $\gamma_{\rm st}(G)=8$  and  $\gamma_{\rm st}(G/v)=9$ .

**Proof.** First we obtain the upper bound. Suppose that D is a  $\gamma_{\rm st}$ -set of G. First suppose that  $v \in D$ . If  $u \in N(v)$  is the vertex with the maximum degree among others, then  $(D \cup \{u\}) \setminus \{v\}$  is a strong dominating set of G, because each vertex is strong dominated by the same vertex as before or possibly by u. Now suppose that  $v \notin D$ . If  $w \in N(v)$  is the vertex with the maximum degree among others, then by the same argument,  $D \cup \{w\}$  is a strong dominating set of G. Therefore we have  $\gamma_{\rm st}(G/v) \leq \gamma_{\rm st}(G) + 1$ . To show that this bound is tight, consider graphs G and G/v in Figure 3. One can easily check that the set of black vertices is a  $\gamma_{\rm st}$ -set of both graphs, and therefore  $\gamma_{\rm st}(G/v) = \gamma_{\rm st}(G) + 1 = 8 + 1 = 9$ . Now, we obtain the lower bound. To show the lower bound, first we form G/v. Suppose that S is a  $\gamma_{\rm st}$ -set of G/v. We remove all the added edges and add v to form G. We consider the following cases:

- (i)  $N(v) \subseteq S$ . Clearly  $S \cup \{v\}$  is a strong dominating set of G and we have  $\gamma_{\rm st}(G) \le \gamma_{\rm st}(G/v) + 1$ .
- (ii)  $N(v) \subseteq V \setminus S$ . So  $S \cup \{v\}$  is a strong dominating set of G, because each vertex is strong dominated by the same vertex as before (and possibly v). So  $\gamma_{\rm st}(G) \le \gamma_{\rm st}(G/v) + 1$ .
- (iii) For all vertices  $u \in N(v)$ ,  $\deg_G(v) \ge \deg_G(u)$ . So by the same argument as Case (ii),  $S \cup \{v\}$  is a strong dominating set of G, and  $\gamma_{\rm st}(G) \le \gamma_{\rm st}(G/v) + 1$ .

- (iv) There exists a vertex  $u \in N(v) \cap S$  such that  $\deg_G(u) \ge \deg_G(v)$ . So  $S \cup N(v)$  is a strong dominating set of G, because v is strong dominated by u and the rest of vertices are strong dominated by the same vertices as before. So  $\gamma_{\rm st}(G) \le \gamma_{\rm st}(G/v) + \deg(v) 1$ .
- (v) There exists a vertex  $u \in N(v) \cap (V \setminus S)$  such that  $\deg_G(u) \ge \deg_G(v)$ . If  $N(v) \subseteq V \setminus S$ , then it is Case (ii). So suppose that there exists a vertex w such that  $w \in N(v) \cap S$ . Then similar to Case (iv),  $S \cup N(v)$  is a strong dominating set of G, since v is strong dominated by u, and we are done.

Hence in general, we have  $\gamma_{\rm st}(G/v) \geq \gamma_{\rm st}(G) - \deg(v) + 1$ . Now, we show that this bound is tight. Consider graphs G and G/v in Figure 4. The set of black vertices is a  $\gamma_{\rm st}$ -set of both graphs, and  $\gamma_{\rm st}(G/v) = \gamma_{\rm st}(G) - \deg(v) + 1 = 20 - 4 + 1 = 17$ .

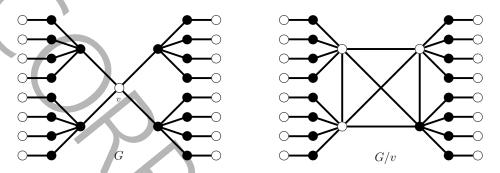

Figure 4: Graphs G and G/v with  $\gamma_{\rm st}(G)=20$  and  $\gamma_{\rm st}(G/v)=17$ .

**Theorem 2.3.** Let G = (V, E) be a connected graph and  $v \in V$  be a pendant vertex such that  $uv \in E$ . Then,

$$\gamma_{\mathrm{st}}(G) - 1 \le \gamma_{\mathrm{st}}(G/v) \le \gamma_{\mathrm{st}}(G) + \deg(u) - 1.$$

Furthermore, these bounds are tight.

**Proof.** First we consider the upper bound. Suppose that D is a  $\gamma_{st}$ -set of G. So clearly  $u \in D$ . We have the following cases:

- (i) u do not strong dominate other vertices except v. Then D is strong dominating set of G/v and we have  $\gamma_{\rm st}(G/v) \leq \gamma_{\rm st}(G)$ .
- (ii) u strong dominate  $w \neq v$  and  $\deg_G(u) \geq \deg(w) + 1$ . Then  $(D \cup N(u)) \setminus \{w\}$  is strong dominating set of G/v and we have  $\gamma_{\rm st}(G/v) \leq \gamma_{\rm st}(G) + \deg(u) 1$ , because all vertices are strong dominating by the same vertices as before.
- (iii) u strong dominate  $w \neq v$  and  $\deg_G(u) = \deg(w)$ . Then  $(D \cup N(u)) \setminus \{u\}$  is strong dominating set of G/v and we have  $\gamma_{\rm st}(G/v) \leq \gamma_{\rm st}(G) + \deg(u) 1$ , because all vertices are strong dominated by the same vertices as before, and u is strong dominated by w.

Hence  $\gamma_{\rm st}(G/v) \leq \gamma_{\rm st}(G) + \deg(u) - 1$ . Now we show that this bound is tight. Consider graph G in Figure 5. One can easily check that the set of black vertices is a  $\gamma_{\rm st}$ -set of G, say S, and we have  $\gamma_{\rm st}(G) = 17$ , and  $(S \cup N(u)) \setminus \{u\}$  is a  $\gamma_{\rm st}$ -set of G/v, and we have  $\gamma_{\rm st}(G/v) = 20$ . Now, we consider the lower bound. First, we form G/v and find a  $\gamma_{\rm st}$ -set of G/v, say D. Then one can easily check that  $D \cup \{u\}$  is a strong dominating set of G, and we have  $\gamma_{\rm st}(G) \leq \gamma_{\rm st}(G/v) + 1$ . If we consider G as path graph of order 3k + 1, where  $k \in \mathbb{N}$ , then we see that  $\gamma_{\rm st}(G/v) = \gamma_{\rm st}(G) - 1$ , and the tightness holds.

We have the following result as an immediate outcome of Theorem 2.3.

Corollary 2.4. If G = (V, E) is a connected graph and  $e = uv \in E$  such that v is the pendant vertex, then

$$\gamma_{\rm st}(G) - 1 \le \gamma_{\rm st}(G/e) \le \gamma_{\rm st}(G) + \deg(u) - 1.$$

Here we consider a modified graph which is obtained by another operation on a vertex. We denote by  $G \odot v$  the graph obtained from G by the removal of all edges between any pair of neighbors of v, note v is not removed from the graph. This operation removes triangles from the graph and for the first time has considered for computation of domination polynomial of a graph, which is the generating function for the number of dominating sets of graphs ([2]).

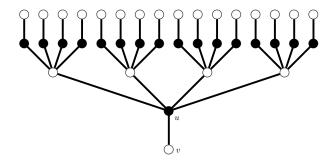

Figure 5: Graph G with  $\gamma_{\rm st}(G) = 17$  and  $\gamma_{\rm st}(G/v) = 20$ .

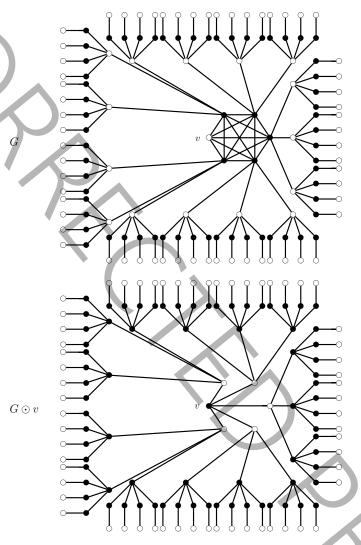

Figure 6: Graphs G and  $G \odot v$  with  $\gamma_{\rm st}(G) = 65$  and  $\gamma_{\rm st}(G \odot v) = 76$ .

**Theorem 2.5.** Let G = (V, E) be a connected graph and  $v \in V$ . Then

$$\gamma_{\mathrm{st}}(G \odot v) \leq \gamma_{\mathrm{st}}(G) + 1 - 2\deg_G(v) + \sum_{u \sim v} \deg_{G \odot v}(u).$$

Furthermore, this bound is tight.

**Proof.** If v is a pendant vertex, then we have nothing to prove, because  $\gamma_{\rm st}(G \odot v) = \gamma_{\rm st}(G)$ . So in the following, suppose that v is not a pendant vertex, and D is a  $\gamma_{\rm st}$ -set of G. If  $x \in N(v) \cap D$ , and does not strong dominate other vertices, then we simply keep it for strong dominating set of  $G \odot v$ , and add v to D. If  $x \in N(v) \cap (V \setminus D)$ , then we add v and add v to v. So, in every cases, all  $v \in N(v)$  are strong dominate some other vertices, and these

vertices are not in N(v). Suppose that the vertex x strong dominate the vertex y and  $y \notin N(v)$ . If after forming  $G \odot v$ ,  $\deg_{G \odot v}(x) \ge \deg(y)$ , then we just add v to D. But sometimes, we need to add all neighbours of x to D and remove x from D. So in this case, The set

$$D' = (D \setminus N(v)) \cup \{v\} \bigcup_{u \sim v} (N_{G \odot v}(u) \setminus \{v\}),$$

is a strong dominating set of  $G \odot v$  with the biggest size other than what ever we mentioned before, and we have

$$\gamma_{\mathrm{st}}(G \odot v) \leq \gamma_{\mathrm{st}}(G) + 1 - \deg_G(v) + \sum_{u \sim v} (\deg_{G \odot v}(u) - 1),$$

and we are done. Now, we show that this bound is tight. Consider graph G and  $G \odot v$  in Figure 6. One can easily check that the set of black vertices is a  $\gamma_{\rm st}$ -set of both graphs, and we have  $\gamma_{\rm st}(G) = 65$  and  $\gamma_{\rm st}(G \odot v) = 76$ . Therefore the equality holds.
